

Quantum entanglement is a physical phenomenon that occurs when pairs or groups of particles are generated, interact, or share spatial proximity in ways such that the quantum state of each particle cannot be described independently of the state of the others. This phenomenon was famously described by Albert Einstein as 'spooky action at a distance,' because changes to one entangled particle seem to instantaneously affect the other, no matter the distance separating them. Entanglement has been experimentally verified numerous times and is a foundational element in quantum mechanics. It has practical applications in emerging technologies such as quantum computing, quantum cryptography, and quantum teleportation. The importance of quantum entanglement extends into discussions about the nature of reality, locality, and the limits of human understanding of the universe. Einstein, Podolsky, and Rosen (EPR) published a paper in 1935 challenging the completeness of quantum mechanics based on entanglement, leading to the famous EPR paradox. Later experiments, particularly those based on Bell's Theorem, provided strong evidence against local hidden variable theories and for the existence of entanglement.
